EduGenie: Google Gemini Powered Learning Assistant

Vetri Thiran Payirchi Thittam

Topic: Select AI Model

1. Introduction

EduGenie is a learning-assistant application designed to help students learn, ask questions, summarize content, and receive AI-powered explanations. The project uses Google Gemini models through the Gemini API to provide generative-AI capabilities. Google documents that Gemini API models can be selected and used for tasks such as text generation, multimodal understanding, and conversational applications.

2. Objective of Selecting the AI Model

The main objective is to select a suitable Gemini model that provides a good balance between response quality, speed, capability, and project requirements. The selected model should support the educational features required by EduGenie.

3. Model Selection

For the EduGenie prototype, a Flash-family Gemini model can be selected when fast responses and efficient operation are important. Google's current Gemini model documentation lists Gemini 3.8 Flash as a stable model and describes it as suitable for complex software-engineering, agentic, and everyday workloads. The exact model name should be configured according to the model currently available to the project's API account.

Requirement	Why it matters in EduGenie
Fast response	Students receive answers quickly during interactive learning.
Text generation	Useful for explanations, summaries, notes, and question answering.
Reasoning	Helps with step-by-step explanations and academic problem solving.
Multimodal capability	Can support learning scenarios involving supported non-text inputs.
Scalability	The model can be integrated through the Gemini API in the application.

4. Selection Process

Step 1: Identify the main EduGenie features and expected AI tasks.
Step 2: Check the currently available Gemini models and their capabilities.
Step 3: Compare response speed, reasoning capability, supported inputs, cost considerations, and limits.
Step 4: Select an appropriate stable model for the prototype.
Step 5: Configure the selected model in the Gemini API integration and test it with sample educational prompts.

5. Example Model Configuration

A model identifier is passed to the Gemini API when creating a model interaction. For example, Google's current API documentation demonstrates using the model identifier **gemini-3.8-flash**. Model availability can change, so the project should verify the current model list before deployment.

6. Expected Output in EduGenie

After selecting and configuring the AI model, EduGenie can use it to generate educational answers,

explain difficult concepts in simple language, create summaries, and support an interactive question-and-answer experience.

7. Conclusion

Selecting the AI model is an important step in building EduGenie. A suitable Gemini Flash model can provide a practical combination of speed and AI capability for an educational assistant. The final model should always be selected based on the current Gemini API documentation and the specific requirements of the deployed application.
